# SAFEPATH

## Week 1 Deliverables — Requirement Analysis & Planning

### 1. Competitor App Analysis

Existing women/personal-safety apps were studied to identify gaps. Most rely on a manual SOS trigger and offer no predictive or automatic protection:

| App | Key Features |
|---|---|
| bSafe | SOS alert, live video/audio streaming, fake call, voice-activated SOS |
| Life360 | Family location sharing, crash detection, geofencing alerts |
| My Safetipin | Static area safety score (lighting, crowd) — not real-time or route-based |
| Himmat App (Delhi Police) | One-tap SOS to police, manual audio/video recording, GPS tracking |
| 112 India App | Panic button linked to national emergency services |
| VithU | Power-button SOS, auto location alert every 2 minutes |
| Smart24x7 | SOS alert, fake call, silent-mode trigger, live tracking |

*Conclusion: existing apps are reactive and manual-trigger based. SafePath's core novelty is being predictive and autonomous.*

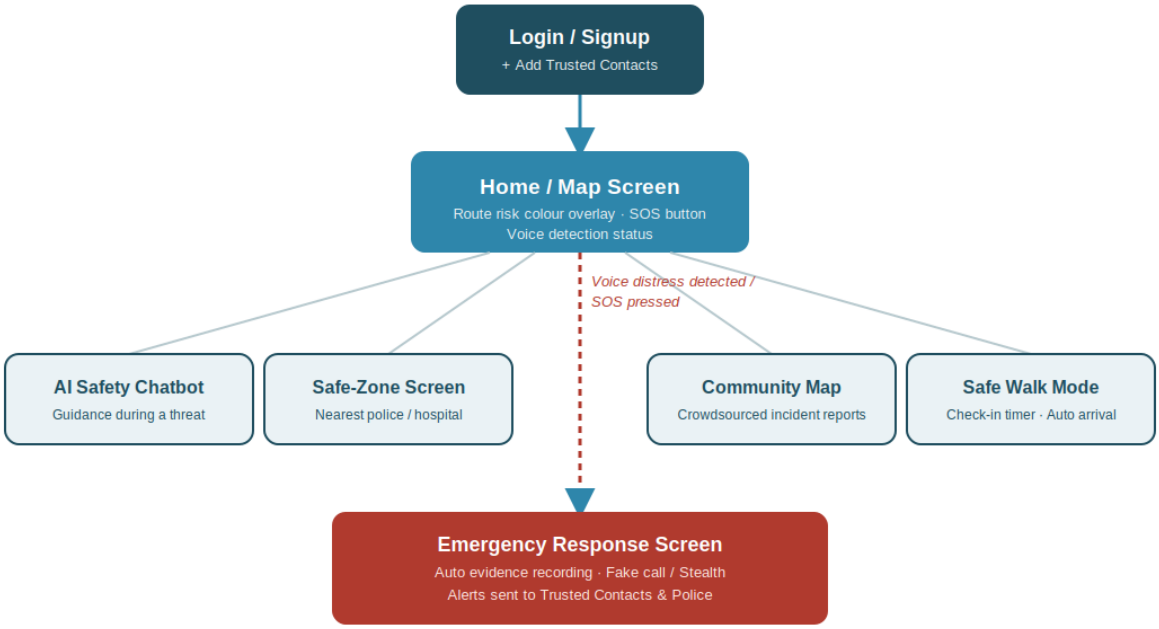

### 2. Finalized Feature List

Based on the above research, the following 11 features were finalized for SafePath:

- Real-Time Route Risk Prediction — crime data, time, crowd density
- Voice-Based Distress Detection — on-device, privacy-safe
- AI Safety Chatbot — real-time contextual guidance
- Automatic Evidence Collection — audio/video/GPS/timestamp
- Emergency Alerts to Trusted Contacts
- Safe-Zone Recommendations
- Safe Walk Mode
- Auto Check-In (Geofencing)
- Offline SOS via SMS
- Community Incident Map
- Fake Call & Stealth Mode

### 3. App Screen Flow

The navigation flow below shows how a user moves through the app, and how an emergency automatically routes to the response screen without manual steps.

## 4. System Architecture

The overall technical architecture connecting the mobile app, backend, ML models, and data sources:
